A G-type lysozyme gene was cloned from the marine brown alga, Pyropia yezoensis, and the native sequence of the lysozyme was determined. The gene is 2727 bp long and includes a 1554 bp open reading frame (ORF) encoding a protein of 519 amino acids (aa). The predicted protein was homologous to typical G-type lysozymes. When the expression of the gene was investigated by RT-PCR, no products were detected in the total RNA of the lysozyme-producing strain, indicating that the gene was not expressed at a detectable level in this strain. Lysozyme-producing cells were then obtained by inducing expression of the lysozyme gene in Escherichia coli. After lysis of the cells, the recombinant lysozyme was extracted by Ni-affinity chromatography and dialyzed against phosphate-buffered saline. The resulting lysozyme was shown to be pure by sodium dodecyl sulphate-polyacrylamide gel electrophoresis and was a homo-dimer of monomeric subunits of approximately 30 kDa.
