The emulator was tested in 2 browsers (Windows and Linux), using multiple proxies, and using 3 different operating systems: Windows 10, Windows 8.1, and Windows 7. Checkmate is a piece sacrifice in chess. A player may sacrifice a piece to gain checkmate. By doing this, the player intends to force the opponent to lose all their remaining pieces. This is also called an "attack" by the player. Or, in other words, the player wishes to force his opponent to drop the remaining pieces rather than any more of them. Checkmate is a win for the player, rather than for the objective of the game. While checkmate is a win, this may not be the end of the game. There are other outcomes that may occur. In the case of a draw, each player will have 7 or 8 remaining pieces. The game may continue with a player generating a single "material" piece to try to force the other player into checkmate. This only works if the opponent cannot absorb the piece. An alternative scenario is for one player to make a stronger move so that the other player is checkmated without any material piece. While alpha-numeric combination files tend to be very easy to recreate, combinations of graphic images are extremely difficult. This makes a closed source combination file of binaries, the source code, and any documents unique to a computer very difficult to recreate. We could not find any combination files with more than 1000 combinations where the game and arrangement were printed on the same page, the printable area of a sheet of paper or computer paper. This page describes how we were able to recreate combinations of up to 1000 combinations of checkmate. The process may be able to create more combinations if additional time and resources were put into it.
